Volunteer Lake monitoring report*

Stoney (Siler) Lake

2007 Report

Completed with support from:

Alberta Lake Management Society

Address: PO Box 4283, Edmonton,
Alberta, T6E 4T3

Phone: 780-702-ALMS

E-mail: info@alms.ca

And you really live by the river? What a jolly life!"

"By it and with it and on it and in it," said the Rat. "It's brother and sister to me. What it hasn't got is not worth having, and what it doesn't know is not worth knowing." Kenneth Grahame The Wind in the Willows

"The world's supply of fresh water is running out. Already one person in five has no access to safe drinking water."

BBC World Water Crisis Homepage

Alberta Lake Management Society's Lakewatch Program

Lakewatch has several important objectives, one of which is to collect and interpret water quality on Alberta Lakes. Equally important is educating lake users about their aquatic environment, encouraging public involvement in lake management, and facilitating cooperation and partnerships between government, industry, the scientific community and lake users. Lakewatch Reports are designed to summarize basic lake data in understandable terms for a lay audience and are not meant to be a complete synopsis of information about specific lakes. Additional information is available for many lakes that have been included in Lakewatch and readers requiring more information are encouraged to seek these sources.

ALMS would like to thank all who express interest in Alberta's aquatic environments and particularly those who have participated in the Lakewatch program. These people prove that ecological apathy can be overcome and give us hope that our water resources will not be the limiting factor in the health of our environment.

Acknowledgements

The Lakewatch program is made possible through the dedication of its volunteers and the Lakewatch Chairs, Théo Charette and Ron Zurawell. We would like to thank George Roberts and Eryl Roberts for their efforts in collecting data during 2007. Numerous Alberta Environment staff also contributed to successful completion of the 2007 program. We would like to thank Jill Anderson and Wendy Markowski who were summer interns with ALMS in 2007. Project Technical Coordinator, Megan McLean was instrumental in planning and organizing the field program. Technologists, Mike Bilyk, Brian Jackson and John Willis were involved in the logistics planning and training aspects of the program. Doreen LeClair was responsible for data management. Théo Charette (ALMS Director) was responsible for program administration and planning. Théo Charette, Ron Zurawell (Limnologist, AENV), and Lori Nuefeld prepared the original report, which was updated by Heather Powell in 2007. The Lakewatch program was financially supported by Alberta Environment and Lakeland Industry and Community Association (LICA).

Stoney Lake

Stoney (Siler) Lake is located 13 km west of Elk Point on Hwy 646 (Township Road 565) (Figure 1).

Stoney Lake has a surface area of 2.34 km² (determined using ArcHydro, M. Raven, personal communication, 2008) and drains an area = 138.76 km² (M. Raven, 2008). The lake is situated in the Boreal forest region, although the lake is also within the Agricultural Use Area of the County of St. Paul Municipal Development Plan (CSP 2007). The lake has recreational and camping facilities nearby. Sport fish include pike and perch.

Figure 1. Stoney (Siler) Lake, Alberta. From Google Earth 2007.

Results

Water Levels

Water levels in Stoney Lake were not available. However, water levels in nearby Lac Bellevue have been monitored since 1969. Peak water level occurred in July 1974 (646.9 meters above sea level (asl)). Water level elevation has steadily declined since 1974 (Figure 3). The lowest water level was recorded in October 2002 (elevation = 643.7 m asl). Changes in lake water levels may be an important concern for Lac Bellevue. If water level decline is due to either changes in precipitation

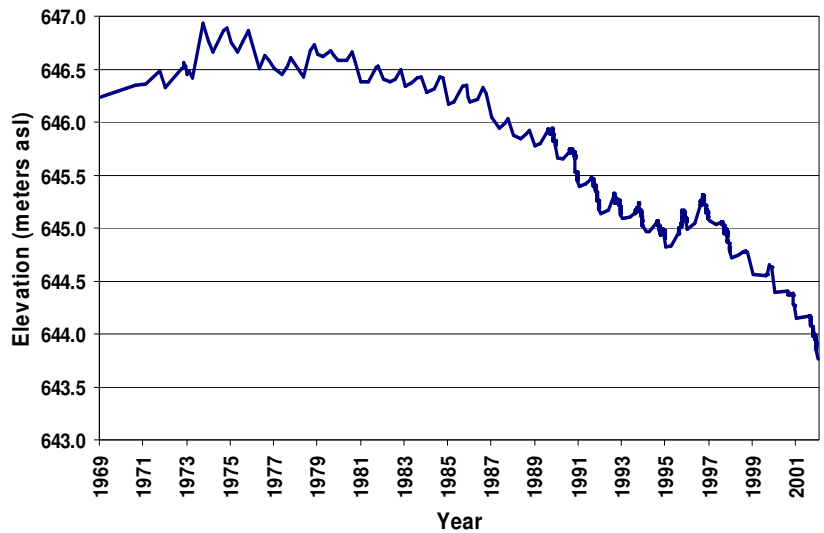

Figure 2. Lake water elevation (meters above sea level (asl)) in Lac Bellevue, Alberta, 1969-2002.

or to agricultural activities, it is possible that Stoney Lake experiences similar pressures. Water levels should be monitored in Stoney Lake in order to determine trends in water levels as well as to identify land use activities which may potentially alter Stoney Lake water levels.

Water Temperature and Dissolved Oxygen

Water temperature and dissolved oxygen profiles in the water column can provide information on water quality and fish habitat. Please refer to the end of this report for descriptions of technical terms.

Stoney Lake mixes intermittently throughout the summer (e.g. polymictic), as is evidenced by the lack of strong thermal stratification during late June, August, and September (**Figure 3**). In early June, a thermocline was evident at 2m depth. The lake mixed prior to the 28 June sample date and no thermocline was evident. A thermocline was again established by 16 July at 3 m depth. The lake mixed again in early August and water temperature was ~15°C at all depths. Maximum surface water temperature was measured on 16 July 2007. Minimum surface water temperature was measured on 13 September 2007.

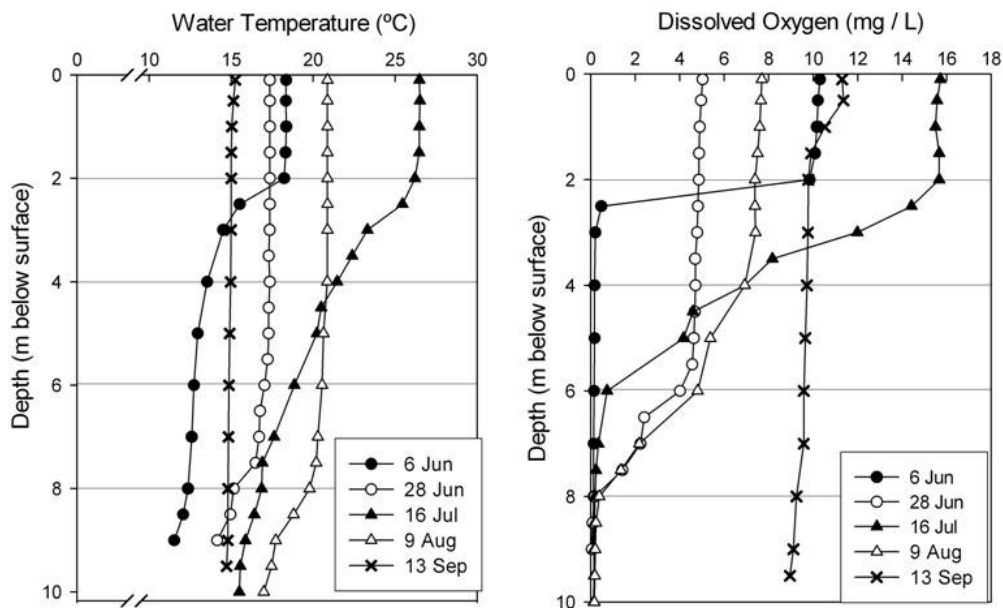

Figure 3. Water temperature (°C) and dissolved oxygen (mg /L) profiles for Stoney (Siler) Lake during the summer of 2007.

Dissolved oxygen levels in the lake followed a similar pattern (**Figure 3**). In early June, dissolved oxygen (DO) concentration declined to near zero (e.g. anoxic) at 2 m depth. When the lake mixed during mid-June, DO was ~5 mg/L from the surface to ~6m depth. The DO profile stratified again on 16 July and DO concentrations in surface waters

increased to ~16 mg/L. This temperature extended to 2m depth. Below 2m, DO declined rapidly and neared 0 mg/L at 5m depth. Stoney Lake mixed again between the July and August sample dates. The DO profile on 9 August was similar to the profile measured on 28 June. The DO profile on 13 September suggests the lake fully over-turned in early-mid September.

Anoxic conditions near the lake bed reflect decomposition, which consumes oxygen. The oxygen levels in surface layers of Stoney Lake were within the acceptable range for surface water quality, according to Alberta Environment guidelines ($DO \geq 5.0$ mg/L).

Water Clarity and Secchi Depth

Water clarity is influenced by suspended materials, both living and dead, as well as some coloured dissolved compounds in the water column. During the melting of snow and ice in spring, lake water can become cloudy from silt transported into the lake. Lake water usually clears in late spring but then becomes more turbid with increased algal biomass as the summer progresses. The easiest and most widely used measure of lake water clarity is the Secchi disk depth.

Compared to shallower lakes, Stoney Lake appears relatively clear, with an average Secchi depth = 1.98 meters. During the summer of 2007, light penetrated to an average 21% of the total lake depth (**Table 1**), thus algae were able to grow through nearly a quarter of the water column. Water clarity was highest on 28 June and declined over the summer. The water clarity pattern is correlated with algal biomass (**Figure 4**). As algae grow throughout the summer, water clarity declined and was 0.9 m on 13 September. The pattern of water clarity is common for polymictic lakes, which re-suspend particles in the water column during mixing events.

Water Chemistry

Based on lake water characteristics, Stoney Lake is classified as hypereutrophic (see *A Brief Introduction to Limnology* at end of this report). This is evidenced by high concentrations of total phosphorus (average TP = 109.6 $\mu\text{g/L}$) and total Kjeldahl nitrogen (average TN = 1.97 mg/L) and high algal biomass (average chl *a* = 33.3 $\mu\text{g/L}$) (**Figure 4**).

Phosphorous and nitrogen concentrations peaked in September (**Figure 4**). As nutrient concentrations increased, algal biomass increased. Algal abundance was at a minimum on 28 June, which coincides with a mixing event in the lake. Thus, during late June, algal growth may have been inhibited by sediment re-suspension during mixing.

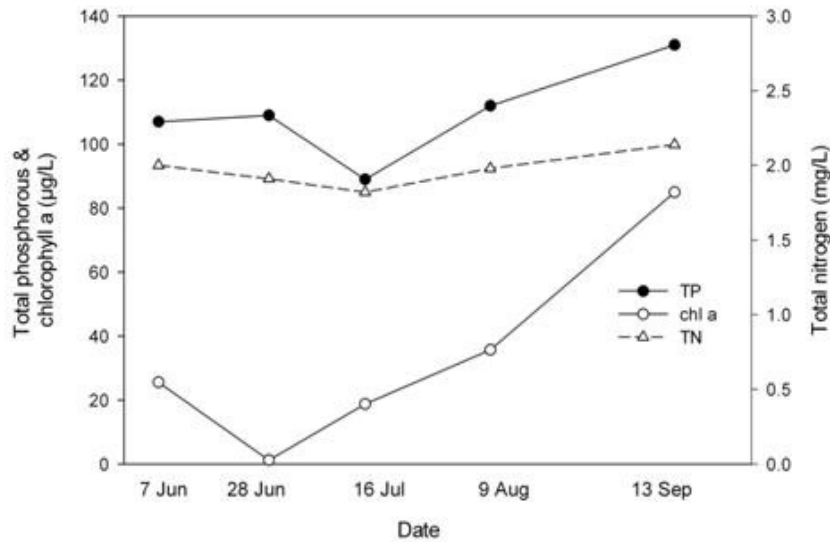

Figure 4. Total phosphorus, total nitrogen, and chlorophyll α (a measure of algae biomass) concentrations for Stoney (Siler) Lake during the summer of 2007.

The increase in nutrient concentrations in late summer may be influenced by surrounding land-use activities, such as agriculture and recreation.

Stoney Lake is well-buffered from acidification. In 2007, lake pH = 8.9 is well above that of pure water (i.e., pH 7). Dominant ions are bicarbonate, sodium, sulphate, and magnesium (**Table 1**). As no historical data were available for Stoney Lake, it is difficult to detect changes in water chemistry.

The average concentrations of heavy metals (as total recoverable concentrations) in Stoney Lake were below CCME guidelines for the Protection of Freshwater Aquatic Life (**Appendix 1**).

Table 1. Mean water chemistry in Stoney (Siler) Lake, Alberta summer 2007.

Parameter	2007
TP ($\mu\text{g/L}$)	109.6
TDP ($\mu\text{g/L}$)	57.4
Chlorophyll <i>a</i> ($\mu\text{g/L}$)	33.3
Secchi disk depth (m)	1.98
TN (mg/L)	1.97
NO ₂₊₃ ($\mu\text{g/L}$)	<0.005
NH ₄ ($\mu\text{g/L}$)	149.2
Dissolved organic C (mg/L)	20.6
Ca (mg/L)	27.3
Mg (mg/L)	41.2
Na (mg/L)	78.7
K (mg/L)	15.9
SO ₄ (mg/L)	75.3
Cl (mg/L)	12.2
CO ₃ (mg/L)	30
HCO ₃ (mg/L)	322.7
Total Alkalinity (mg/L CaCO ₃)	315
pH	8.9
Conductivity ($\mu\text{S/cm}$)	718
Total dissolved solids (mg/L)	439.7

Note: TP = total phosphorus, TDP = total dissolved phosphorus, Chla = chlorophyll *a*, TN= total Kjeldahl nitrogen, NO₂₊₃ = nitrate+nitrite, NH₄ = ammonium, Ca = calcium, Mg = magnesium, Na = sodium, K = potassium, SO₄ = sulphate, Cl = chloride, CO₃ = carbonate, HCO₃ = bicarbonate.

FLUORIDE mg/L	-	-	-	-	1.5

With the exception of fluoride (which reflects the mean concentration of dissolved fluoride only), values represent means of total recoverable metal concentrations.

^a Based on pH ≥ 6.5; calcium ion concentration [Ca⁺²] ≥ 4 mg/L; and dissolved organic carbon concentration [DOC] ≥ 2 mg/L.

^b Based on water Hardness of 300 mg/L (as CaCO₃).

^c Based on water Hardness > 180 mg/L (as CaCO₃).

^d CCME interim value.

^e Based of Canadian Drinking Water Quality guideline values.

^f Based of CCME Guidelines for Agricultural Use (Livestock Watering).

^g Based of CCME Guidelines for Agricultural Use (Irrigation).

* - not a mean value. One value measured during summer.

A brief introduction to Limnology

Indicators of water quality

The goal of **Lakewatch** is to collect water samples necessary to determine the water quality of lakes. Though not all encompassing, the variables measured in **Lakewatch** are sensitive to human activities in watersheds that may cause impacts to water quality. For example, nutrients such as phosphorus and nitrogen are important determinants of lake productivity. The concentrations of these nutrients in a lake are affected (typically elevated) by land use changes such as increased crop production or livestock grazing. Elevated nutrient concentrations can cause increases in undesirable algae blooms resulting in low dissolved oxygen concentrations, degraded fish habitat and production of noxious odors. Large increases in nutrients over time may also indicate sewage inputs, which in turn, may result in other human health concerns such as harmful bacteria or protozoans (e.g. *Cryptosporidium*).

Temperature and mixing

Water temperature in a lake dictates the behavior of many chemical parameters responsible for water quality (Figure 6). Heat is transferred to a lake at its surface and slowly moves downward depending on water circulation in the lake. Lakes with a large surface area or a small volume tend to have greater mixing due to wind. In deeper lakes, circulation is not strong enough to move warm water to depths typically greater than 4 or 5 m and as a result cooler denser water remains at the bottom of the lake. As the difference in temperature between warm surface and cold deeper water increases, two distinct layers are formed. Limnologists call these layers of water the **epilimnion** at the surface and the **hypolimnion** at the bottom. The layers are separated by a transition layer known as the **metalimnion** which contains the effective wall separating top and bottom waters called a **thermocline**. A thermocline typically occurs when water temperature changes by more than one degree within one-meter depth. The hypolimnion and epilimnion do not mix, nor do elements such as oxygen supplied at the surface move downward into the hypolimnion. In the fall, surface waters begin to cool and eventually reach the same temperature as hypolimnetic water. At this point the water mixes from top to bottom in what is called a **turnover** event. Surface water cools further as ice forms and again a thermocline develops this time with 4° C water at the bottom and 0° C water on the top.

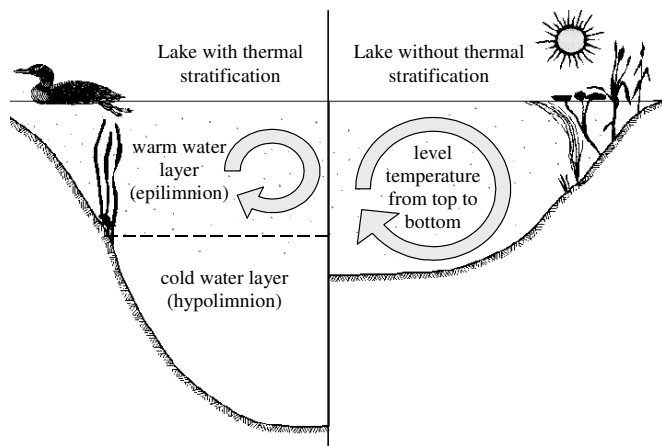

Figure 6: Difference in the circulation of the water column depending on thermal stratification.

In spring another turnover event occurs when surface waters warm to 4° C. Lakes with this mixing pattern of two stratification periods and two turnover events are called **dimictic** lakes. In shallower lakes, the water column may mix from top to bottom most of the ice-free season with occasional stratification during periods of calm warm conditions. Lakes that mix frequently are termed **polymictic** lakes. In our cold climate, many shallow lakes are **cold monomictic** meaning a thermocline develops every winter, there is one turnover event in spring but the remainder of the ice-free season the lake is polymictic.

Dissolved Oxygen

Oxygen enters a lake at the lake surface and throughout the water column when produced by photosynthesizing plants, including algae, in the lake. Oxygen is consumed within the lake by respiration

of living organisms and decomposition of organic material in the lake sediments. In lakes that stratify (see temperature above), oxygen that dissolves into the lake at the surface cannot mix downward into the hypolimnion. At the same time oxygen is depleted in the hypolimnion by decomposition. The result is that the hypolimnion of a lake can become **anoxic**, meaning it contains little or no dissolved oxygen. When a lake is frozen, the entire water column can become anoxic because the surface is sealed off from the atmosphere. Winter anoxic conditions can result in a fish-kill which is particularly common during harsh winters with extended ice-cover. Alberta Surface Water Quality Guidelines suggest dissolved oxygen concentrations (in the epilimnion) must not decline below 5 mg/L and should not average less than 6.5 mg/L over a seven-day period. However, the guidelines also require that dissolved oxygen concentrations remain above 9.5 mg/L in areas where early life stages of aquatic biota, particularly fish, are present.

General Water Chemistry

Water in lakes always contains substances that have been transported by rain and snow or have entered the lake in groundwater and inflow streams. These substances may be dissolved in the water or suspended as particles. Some of these substances are familiar minerals, such as sodium and chloride, which when combined form table salt, but when dissolved in water separate into the two electrically charged components called **ions**. Most dissolved substances in water are in ionic forms and are held in solution due to the polar nature of the water molecule. **Hydrophobic** (water-fearing) compounds such as oils contain little or no ionic character, are non-polar and for this reason do not readily dissolve in water. Although hydrophobic compounds do not readily dissolve, they can still be transported to lakes by flowing water. Within individual lakes, ion concentrations vary from year to year depending on the amount and mineral content of the water entering the lake. This mineral content can be influenced by the amount of precipitation and other climate variables as well as human activities such as fertilizer and road salt application.

Phosphorus and Nitrogen

Phosphorus and nitrogen are important nutrients limiting the growth of algae in Alberta lakes. While nitrogen usually limits agricultural plants, phosphorus is usually in shortest supply in lakes. Even a slight increase of phosphorus in a lake can, given the right conditions, promote algal blooms causing the water to turn green in the summer and impair recreational uses. When pollution originating from livestock manure and human sewage enters lakes not only are the concentrations of phosphorus and nitrogen increased but nitrogen can become a limiting nutrient which is thought to cause blooms of toxic algae belonging to the cyanobacteria. Not all cyanobacteria are toxic, however, the blooms can form decomposing mats that smell and impair dissolved oxygen concentrations in the lake.

Chlorophyll-a

Chlorophyll-*a* is a photosynthetic pigment that green plants, including algae, possess enabling them to convert the sun's energy to living material. Chlorophyll-*a* can be easily extracted from algae in the laboratory. Consequently, chlorophyll-*a* is a good estimate of the amount of algae in the water. Larger aquatic plants, known as macrophytes, rather than algae, dominate some highly productive lakes. In these lakes, chlorophyll-*a* and nutrient values taken from water samples do not include productivity from large aquatic plants. As a result, lakes like Chestermere, which are dominated by macrophytes, can exist at a lower trophic state than if macrophyte biomass was included. Unfortunately, the productivity and nutrient cycling contributions of macrophytes are difficult to sample accurately and are therefore not typically included in trophic state indices.

Secchi Disk Depth

Lakes that are clear are more attractive for recreation, whereas those that are turbid or murky are considered by lake users to have poor water quality. Secchi disk depth is the oldest, simplest, and quickest quantitative measure of water clarity. A Secchi disk is a black and white disk that is lowered down through

the water column until it can no longer be seen. Secchi disk depth is the midpoint between the depth at which it disappears when lowered and reappears when it is pulled up again. The Secchi disk depth in lakes with high algal biomass will generally be shallow. However, Secchi disk depth is not only affected by algae. High concentrations of suspended sediments, particularly fine clays or glacial till, are common in plains or mountain reservoirs of Alberta. Mountain reservoirs may have exceedingly shallow Secchi disk depths despite low algal growth and nutrient concentrations.

The euphotic zone, calculated as twice the Secchi disk depth, is the portion of the water column that has sufficient light for aquatic plants to grow. Murky waters, with shallow Secchi depths, can prevent aquatic plants from growing on the lake bottom. Aquatic plants are important because they ensure clear lake water by reducing shoreline erosion and stabilizing lake bottom sediments. Many lakes in Alberta are shallow and have bottom sediments with high concentrations of nutrients. Without aquatic plants, water quality may decline in these lakes due to murky, sediment-laden water and excessive algal blooms. Maintaining aquatic plants in certain areas of a lake is often essential for ensuring good water clarity and a healthy lake as many organisms, like aquatic invertebrates and fish, depend on aquatic plants for food and shelter.

Trophic state

Trophic state is a classification system for lakes that depends on fertility and is a useful index for rating and comparing lakes. From low to high nutrient and algal biomass (as chlorophyll-*a*) concentrations, the trophic states are: **oligotrophic**, **mesotrophic**, **eutrophic** and **hypereutrophic**. The nutrient and algal biomass concentrations that define these categories are shown in table 2 and a graph of Alberta lakes compared by trophic state can be found on the ALMS website. A majority of lakes in Alberta are meso- to eutrophic because they naturally contain high nutrient concentrations due to our deep fertile soils. Thus, lakes in Alberta are susceptible to human impacts because they are already nutrient-rich; any further nutrient increases can bring about undesirable conditions illustrated in Figure 7.

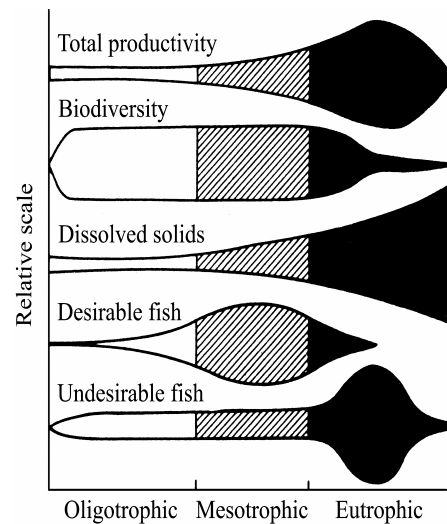

Figure 7: Suggested changes in various lake characteristics with eutrophication. From “Ecological Effects of Wastewater”, 1980.

Table 2: Trophic status based on lake water characteristics

Trophic state	Total Phosphorus (µg/L)	Total Nitrogen (µg/L)	Chlorophyll a (µg/L)	Secchi Depth (m)
Oligotrophic	< 10	< 350	< 3.5	> 4
Mesotrophic	10 - 30	350 - 650	3.5 - 9	4 - 2
Eutrophic	30 - 100	650 - 1200	9 - 25	2 - 1
Hypereutrophic	> 100	> 1200	> 25	< 1

Note: These values are from a detailed study of global lakes reported in Nurnberg 1996. Alberta Environment uses slightly different values for TP and CHL based on those of the OECD reported by Vollenweider (1982). The AENV and OECD cutoffs for TP are 10, 35 and 100; for CHL are 3, 8 and 25. AENV does not have TN or Secchi depth criteria. The corresponding OECD exists for Secchi depth and the cutoffs are 6, 3 and 1.5 m.
